

# WHICH FACTORS AND LINKS WERE MOST FREQUENTLY MENTIONED ?

Similar to overall frequency counts in non-causal coding ("which themes are mentioned most often?"), we can count how often particular causal factors are mentioned, and the number of sources mentioning a factor.

| Factor                   | # Citations |
|--------------------------|-------------|
| Farm production          | 46          |
| Improved health          | 24          |
| Increased knowledge; ... | 23          |

And we can, with caveats, interpret the frequency with which a link is mentioned as the strength of the evidence for that link.

| Cause <span>▲</span>      | Effect <span>▲</span> | Bundle <span>▲</span>             | Source # <span>▲</span> | Citation # <span>▲</span> |
|---------------------------|-----------------------|-----------------------------------|-------------------------|---------------------------|
| <div></div>               | <div></div>           | <div></div>                       |                         |                           |
| Increased knowledge; ...  | Farm production       | Increased knowledge; Farmin...    | 11                      | 23                        |
| Health behaviour; Use ... | Improved health       | Health behaviour; Use pits to ... | 15                      | 15                        |

We can simply make a table with the number of times each factor was mentioned or cited overall, and sort it in descending order to see the most important ones.
